WINTER – 2019 EXAMINATION MODEL ANSWER

Subject: Software Testing Subject Code: 17624

Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

1.	(a) Ans.	Attempt any FIVE of the following: State any two advantages and disadvantages of 'V' model. The advantage of the V-Model method is that it is very easy to understand and apply. The simplicity of this model also makes it easier to manage. The disadvantage is that the model is not flexible to changes and just in case there is a requirement change, which is very common in today's dynamic world, it becomes very expensive to make the change.	5 x 4=20 4M
		 The advantages of the V-Model method are as follows: This is a highly-disciplined model and Phases are completed one at a time. Works well for smaller projects where requirements are very well understood. Simple and easy to understand and use. Easy to manage due to the rigidity of the model. Each phase has specific deliverables and a review process. 	Any two advanta ges 1M each

17624 **Subject Code: Subject: Software Testing** 2) Planning: The purpose of planning phase is to make a schedule, the scope, and resource requirements for a release. A plan explains how the requirements will be met and by which time. At the end of this stage, both project plan and test plan documents are delivered. 3) Design: The purpose of design phase is to figure out how to satisfy the requirements enumerated in SRS. The design phase produces a representation which will be used by the development phase. 4) Development and Coding: The development and coding phase comprises of coding the programs in the chosen programming language. It produces software that meets the requirement and the design. 5) Testing: Testing is process of exercising the software product in predefined ways to check if the behaviour is same as expected behaviour. By testing the product, an organization identifies and removes as many defects as possible before deployment. 6) Deployment and Maintenance: Once a product is tested, it is given to the customers who deploy it in their environments. In maintenance phase wherein the product is maintained or changed to satisfy the changes that arise from customer expectations, environmental changes etc. (d) State how to minimize risk impact while estimating defect. **4M** Minimizing expected impact involves a combination of the following Ans. three strategies: Estimate expected Minimize Identify Critical Descript Risk impact expected impact ion 4M Eliminate the Risk: While this is not always possible or desirable, there are situations where the best strategy will be simply to eliminate the risk altogether. For example, reducing the scope of a system, or deciding not to use the latest unproven technology are ways to eliminate certain risks altogether. • Reduce the Probability of a Risk Becoming a Problem: Most strategies will fall into this category. Inspections and testing are

	examples of approaches that reduce, but do not eliminate, the	
	probability of problems.	
	• Reduce the Impact if there is a Problem: In some situations,	
	the risk cannot be eliminated, and even when the probability of a	
	problem is low, the expected impact is high. In these cases, the best	
	strategy may be to explore ways to reduce the impact if there is a	
	problem. Contingency plans and disaster recovery plans would be	
	examples of this strategy.	
	Once the critical risks are identified, the financial impact of each risk	
	should be estimated. This can be done by assessing the impact, in	
	dollars, if the risk does become a problem combined with the	
	probability that the risk will become a problem. The product of these	
	two numbers is the expected impact of the risk. The expected impact	
	of a risk (E) is calculated as $E = P * I$, where:	
	P= Probability of risk becoming a problem.	
	I= Impact in dollars if risk becoming a problem.

etc. • Static analysis - The code written by developers are analysed (usually by tools) for structural defects that may lead to defects. Following are the types of defects found by the tools during static analysis: Any • A variable with an undefined value. four • Inconsistent interface between modules and components. errors • Variables that are declared but never used. 1M each • Unreachable code (or) Dead Code. • Programming standards violations. • Security vulnerabilities. • Syntax violations. Explain the concept of stub and driver. 4M**(g)** The most common approach to unit testing requires drivers and stubs Ans. to be written. Driver and stubs are special purpose arrangements, generally code, required to test units individually which can act as an input to the unit /module and can take output from unit/module. The driver simulates a calling unit and the stub simulates a called **Explana** unit. A component is not a standalone program; driver and/or stub tion of software must often be developed for each unit test. stub 2M In most applications a driver is nothing more than a "main program" and that accepts test case data, passes such data to the component (to be driver tested) and prints relevant results. Stubs serve to replace modules 2Mthat are subordinate (invoked by) the component to be tested. A stub or "dummy subprogram" uses the sub – ordinate module's interface, may do minimal data manipulation, prints verification of entry and returns control to the module undergoing testing. Both are the software that must be written but that is not delivered with the final software product. Example: Test Driver software Real World Software Results Test case

	Ans.	There are two fundamental approaches to testing software:

		Testing to fail involves testing a feature in every conceivable way

		Once an application or a website has evolved beyond the initial proof

		Staying with the above example, a tester might click button A or

17624 **Subject Code: Subject: Software Testing** • To conduct Stress Testing, sometimes, massive data sets may be used which may get lost during Stress Testing. Testers should not lose this security-related data while doing stress testing. • The main purpose of stress testing is to make sure that the system recovers after failure which is called as recoverability. • For Example, In stress testing of MSBTE online result display, the resources used will be less than the requirement. For e.g. Provide less RAM for the server, or decrease the bandwidth of the internet connection, or provide less hits for page. If the system has limited resources available, the response of the online result system may deteriorate due to non-availability of the resources. It tries to break the page, site or connection under test by overwhelming its resources in order to find the circumstances under which it will crash. It is also a type of load testing. It is designed to determine the behaviour of the software under abnormal situations. In stress testing test cases are designed to execute the system in such a way that abnormal conditions. 49, 50 - for pass 74, 75 - for merit 84, 85 - for distinction

- Boundary values are validated against both the valid boundaries and invalid boundaries. The Invalid Boundary Cases for the above example can be given as follows 0 for lower limit boundary value 101 for upper limit boundary value Boundary value analysis is a black box testing and is also applies to white box testing. Internal data structures like arrays, stacks and queues need to be checked for boundary or limit conditions; when there are linked lists used as internal structures, the behavior of the list at the beginning and end have to be tested thoroughly.
- Boundary value analysis help identify the test cases that are most likely to uncover defects.

Sub-Boundary Conditions

- 1. They're the ones defined in the specification or evident when using the software.
- 2. Some boundaries, though, that are internal to the software aren't necessarily apparent to an end user but still need to be checked by the software tester.

		Use the metrics to provide indicators that will lead to a strategy for improvement.	
		 Product quality: Explicit result of the software development activity, deliverables, products. Product metrics help software engineers to better understand the attributes of models and assess the quality of the software. They help software engineers to gain insight into the design and construction of the software. Focus on specific attributes of software engineering work products resulting from analysis, design, coding, and testing. Provide a systematic way to assess quality based on a set of clearly defined rules. Provide an "on-the-spot" rather than "after-the-fact" insight into the software development. 	
		 Objective Metrics: 1. They are non-negotiable – that is the way they are defined doesn't change with respect to the niche or the type of endeavor they are being applied to. 2. Actual cost or AC is always the total cost actually incurred in accomplishing a certain activity or a sequence of activities. 	
		Subjective Metrics: These metrics are a relatively new precept and are more flexible than the rigid framework of the objective metrics. Subjective metrics do deal with performance but the approach is more tailored. For some enterprises the niche in which they function forces project management to change in order to adapt to the demands of the workplace.

Defect life cycle diagram 2M

The different states of bug life cycle are as shown in the above diagram:

New: When the bug is posted for the first time, its state will be "NEW". This means that the bug is not yet approved.

Open: After a tester has posted a bug, the lead of the tester approves that the bug is genuine and he changes the state as "OPEN".

Assign: Once the lead changes the state as "OPEN", he assigns the bug to corresponding developer or developer team. The state of the bug now is changed to "ASSIGN".

Test/Retest: Once the developer fixes the bug, he has to assign the bug to the testing team for next round of testing. Before he releases the software with bug fixed, he changes the state of bug to "TEST". It specifies that the bug has been fixed and is released to testing team. At this stage the tester do the retesting of the changed code which developer has given to him to check whether the defect got fixed or not.

Deferred: The bug, changed to deferred state means the bug is expected to be fixed in next releases. The reasons for changing the bug to this state have many factors. Some of them are priority of the bug may be low, lack of time for the release or the bug may not have major effect on the software.

WINTER – 2019 EXAMINATION MODEL ANSWER

Subject: Software Testing Subject Code: 170

Rejected: If the developer feels that the bug is not genuine, he rejects the bug. Then the state of the bug is changed to "REJECTED".

Verified: Once the bug is fixed and the status is changed to "TEST", the tester tests the bug. If the bug is not present in the software, he approves that the bug is fixed and changes the status to "VERIFIED".

Reopened: If the bug still exists even after the bug is fixed by the developer, the tester changes the status to "REOPENED". The bug traverses the life cycle once again.

Closed: Once the bug is fixed, it is tested by the tester. If the tester feels that the bug no longer exists in the software, he changes the status of the bug to "CLOSED". This state means that the bug is fixed, tested and approved.

Fixed: When developer makes necessary code changes and verifies the changes then he/she can make bug status as "Fixed" and the bug is passed to testing team.

Pending retest: After fixing the defect the developer has given that particular code for retesting to the tester. Here the testing is pending on the testers end. Hence its status is pending retest.

Optional:

Duplicate: If the bug is repeated twice or the two bugs mention the same concept of the bug, then one bug status is changed to "duplicate".

Not a bug: The state given as "Not a bug" if there is no change in the functionality of the application. For an example: If customer asks for some change in the look and field of the application like change of color of some text then it is not a bug but just some change in the looks of the application.

Project	Project name.						
Product	Product name.						
Release	Release version of the product. (e.g. 1.2.3)						
Version
