

SUMMER – 2019 EXAMINATION  
MODEL ANSWER

Subject: Advanced Microprocessor

Subject Code: 17627

**Important Instructions to examiners:**

- 1) The answers should be examined by key words and not as word-to-word as given in the model answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may try to assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills).
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

Q. No	Sub Q.N.	Answer	Marking Scheme
1.	(a) Ans.	<b>Attempt any FIVE: Explain features of 80386 microprocessor. (any eight)</b> The salient features of 80386 are as follows: 1. It is a 132 PGA (pin grid array) with 32 bits non multiplexed data bus and 32 bits address bus. 2. It works in 3 modes: real, protected and virtual 8086 mode (V-86). 3. It can address total $2^{32}$ i.e., 4GB physical memory with the help of its 32 bits address lines. 4. The integrated memory management unit in 80386 supports segmentation and paging of memory. 5. It supports the interface of 80387-DX coprocessor IC to perform the complex floating point arithmetic operations. 6. It supports 64TB virtual memory. 7. It has an integrated memory management unit which supports the virtual memory and four levels of protections. 8. It has an on chip clock divider circuitry. 9. It has BIST (built in self-test) feature which tests approximately	<b>20 4M</b>  <i>Any eight features <math>\frac{1}{2}</math>M each</i>

	<p>physical address. It allows the size of the segment upto 4GB maximum. It provides the 4 level protection level mechanism for protecting and isolating the system's code and data from application programs and unauthorized access. This unit converts logical address spaces to the linear addresses. The Limit and Attribute PLA checks the segment limits and attributes at segment level to avoid invalid access to the code.</p> <p><b>b. paging unit.</b> The paging unit converts the linear addresses to the physical addresses. The control and attribute PLA checks the privileges at page level. Each of the pages maintain the paging information of the task. The paging unit organizes the physical memory in the terms of pages of 4KB each. This unit works under the control of segmentation unit i.e., each segment is further divided into pages. The virtual memory is also organized in the terms of segments and pages by the MMU.</p> <p><b>3. Bus Interface Unit :</b> BIU is responsible for interfacing the microprocessor with the system with the help of all buses. Control of all buses i.e. address bus, data bus, control bus is in the hands of BIU. The BIU has a bus control unit which has a request prioritizer which resolves the priorities of the various bus request operations. It also controls the access of the bus. The address drivers drives the bus (byte) enable signals BE0#-BE3# and the address signals A0-A31. The pipeline and bus size control unit handle the related control signals and supports the dynamic bus sizing feature. The pipeline unit supports the instruction pipelining feature in 80386. Fetching other instruction while the other is in execution is known as instruction pipelining. The data buffers (mux / transceivers) interface the internal data bus with the system data bus.</p>

- D - DIRTY
- AVAIL - AVAILABLE FOR SYSTEMS PROGRAMMER USE

NOTE: 0 INDICATES INTEL RESERVED. DO NOT DEFINE.

Paging is one of the memory management techniques used for virtual memory multitasking operating system.

- The segmentation scheme may divide the physical memory into a variable size segments but the paging divides the memory into a fixed size pages.
- The segments are supposed to be the logical segments of the program, but the pages do not have any logical relation with the program.
- The pages are just fixed size portions of the program module or data. Thus paging mechanism provides an effective technique to manage the physical memory for multitasking systems.

- **Paging Unit:** The paging unit of 80386 uses a two level table mechanism to convert a linear address provided by segmentation unit into physical addresses.
- The paging unit converts the complete map of a task into pages, each of size 4K. The task is further handled in terms of its page, rather than segments.
- The paging unit handles every task in terms of three components namely page directory, page tables and page itself.

**Paging Descriptor Base Register:** The control register CR2 is used to store the 32-bit linear address at which the previous page fault was detected.

- The CR 3 is used as page directory physical base address register, to store the physical starting address of the page directory.

SUMMER – 2019 EXAMINATION  
MODEL ANSWER

Subject: Advanced Microprocessor

Subject Code: 17627

*Five stages pipeline diagram 4M*

- **The first stage of the pipeline is Prefetch (PF) stage** in which instructions are prefetched from the on-chip instruction cache or memory. Because the Pentium processor has separate caches for instructions and data, prefetches no longer conflict with data references for access to the cache. If the requested line is not in the code cache, a memory reference is made. In the PF stage, two independent pairs of line-size (32-byte) prefetch buffers operate in conjunction with the branch target buffer. This allows one prefetch buffer to prefetch instructions sequentially, while the other prefetches according to the branch target buffer predictions. The prefetch buffers alternate their prefetch paths.
- **The next pipe-line stage is Decode1 (D1)** in which two parallel decoders attempt to decode and issue the next two sequential instructions. The decoders determine whether one or two instructions can be issued contingent upon the instruction pairing rules described in the section titled "Instruction Pairing Rules."

determine whether the condition is met or not.  
The Pentium processor makes the dynamic branch prediction using a Branch Target Buffer (BTB). To efficiently predict branches, the Pentium uses two prefetch buffers. One buffer prefetches code in linear fashion, while the other prefetches instructions based on address in the branch target buffer. As a result the needed code is prefetched before it is required for execution. The Pentium processors prediction algorithm not only forecast the simple branch choices but also supports more complex branch prediction for example, within nested loops. This is achieved by storing multiple branch address in the branch prediction buffer. The design of the branch target buffer allows 256 addresses to be stored and thus the prediction algorithm can forecast up to 256 branches

(c)	<b>Describe the inter MMX architecture w.r.t. its data types &amp; instruction set.</b> <i>(Note : the instruction sets of MMX are not expected in detail from students ,but the registers for the access to these instructions can be explained and shall be given marks)</i>	<b>8M</b>	
<b>Ans.</b>	<b>Instuction sets/ registers:</b> There are 57 new SIMD instructions added to the instructions set of intel MMX for the support of the multimedia functions. For these instructions new 8 general purpose registers have been introduced. The description of which are as given below: 1. In Pentium there are eight general purpose floating point registers in a floating point unit. 2. Each of these eight registers are 80-bit wide for floating point operations, 64 bits are used for mantissa and rest of 16 bit for exponent. 3. Intel MMX instructions use these floating point registers as MMX registers and used only 64 bit mantissa portion of these registers to store MMX operands. 4. Thus MMX programmers virtually get new MMX registers each of 64bits. 5. It is possible to use same set of registers as floating point registers and MMX register in the same program; it is preferable not to use them concurrently.	<i>intel MMX architecture w.r.t. its data types 4M</i>  <i>instructi on sets/regi sters 4M</i>

Subject Code: 17627

CPUs generally use this space to include a large number of registers (> 100 occasionally). The CPU can access data in registers more quickly than data in memory so having more registers makes more data available faster. Having more registers also helps reduce the number of memory references especially when calling and returning from subroutines. The RISC processor may not be able to access all the registers it has at any given time provided that it has many of it. Most RISC CPUs have some global registers which are always accessible. The remaining registers are windowed so that only a subset of the registers is accessible at any specific time. To understand how register windows work, we consider the windowing scheme used by the Sun SPARC processor. The processor can access any of the 32 different registers at a given time. (The instruction formats for SPARC always use 5 bits to select a source/destination register which can take any 32 different values. Of these 32 registers, 8 are global registers that are always accessible. The remaining 24 registers are contained in the register window. The register window overlap. The overlap consists of 8 registers in SPARC CPU. Notice that the organizations of the windows are supposed to be circular and not linear; meaning that the last window overlaps with the first window.

**Example:** the last 8 registers of window 1 are also the first 8 registers of window 2. Similarly, the last 8 registers of window 2 are also the first 8 registers of window 3. The middle 8 registers of window 2 are local; they are not shared with any other window.

	<p><b>2. Memory speed issue:</b> Memory speed issues are commonly solved using caches. A cache is a section of fast memory placed between the processor and slower memory. When the processor wants to read a location in main memory, that location is also copied into the cache. Subsequent references to that location can come from the cache, which will return a result much more quickly than the main memory. Caches present one major problem to system designers and programmers, and that is the problem of coherency. When the processor writes a value to memory, the result goes into the cache instead of going directly to main memory. Therefore, special hardware (usually implemented as part of the processor) needs to write the information out to main memory before something else tries to read that location or before re-using that part of the cache for some different information.</p> <p><b>3. Instruction Latency issue:</b> A poorly designed instruction set can cause a pipelined processor to stall frequently. Some of the more common problem areas are:</p> <p>Highly encoded instructions such as those used on CISC machines that require complex decoders. Those should be avoided. Variable-length instructions which require multiple references to memory to fetch in the entire instruction. Instructions which access main memory (instead of registers), since main memory can be slow. Complex instructions which require multiple clocks for execution (many floating-point operations, for example.) Instructions which need to read and write the same register. For example "ADD 5 to register 3" had to read register 3, add 5 to that value, then write 5 back to the same register (which may still be "busy" from the earlier read operation, causing the processor to stall until the register becomes available.) Dependence on single-point resources such as a condition code register. If one instruction sets the conditions in the condition code register and the following instruction tries to read those bits, the second instruction may have to stall until the first instruction's write completes.</p> <p><b>4. Dependencies issues:</b> One problem that RISC programmers face is that the processor can be slowed down by a poor choice of instructions. Since each instruction takes some amount of time to store its result, and several instructions are being handled at the same time, later instructions may have to wait for the results of earlier instructions to be stored. However, a simple rearrangement of the</p>

		instructions in a program (called Instruction Scheduling) can remove these performance limitations from RISC programs.	
(b) Ans.	<b>List and explain features of Sun Ultra SPARC processor. (Any 8)</b> It contains an integer unit, a FPU and a optional coprocessor. The 64 bits Ultra SPARC architecture has following features : 1. It has 14 stages non-stalling pipeline. 2. It has 6 execution units including two for integer, two for floating point, one for load/store and one for address generation units. 3. It has a large number of buffers but only one load/store unit, it dispatches them one instruction at a time from the instruction stream. 4. It contains 32KB L1 instruction cache, 64KB L1 data cache, 2KB prefetch cache and 2 KB write cache. It also has 1MB on chip L2 cache. 5. Like Pentium MMX it also contains the instructions to support multimedia. These instructions are helpful for the implementation of image processing codes. 6. One of the major limitations of SPARC system is its low speed compared to most of the modern processors. 7. SPARC stores multi-byte numbers using BIG Indian format, i.e. the MSB will be stored at the lowest memory address. 8. It supports a pipelined floating point processor. The FPU has 5 separate functional units for performing the floating point operations. The floating point instructions can be issued per cycle and executed by the FPU unit. The source and data results are stored in 32 register files. Majority of the floating point instructions have a throughput of one cycle and a latency of three cycles. Although the single precision (32 bit) or double precision (64 bit) floating point computations can be performed by hardware, quad precision i.e. 128 bits operation can be performed only in the software.	<b>8M</b>  <i>Any eight features of sun ultra SPARC processor 1M each</i>

SUMMER – 2019 EXAMINATION  
MODEL ANSWER

Subject: Advanced Microprocessor

Subject Code: 17627

	<p>2000, LINUX OS. 2. PIII is incorporated with MMX technology. 3. Dynamic execution, micro-architecture incorporates unique combination of multiple branch prediction, data flow analysis and speculative execution. 4. The Pentium III processor has Multiple low power states. 5. Pentium III is optimized for 32 bits applications running on advanced 32 bits OS. 6. It has 32KB L1 cache divided as 16KB instruction cache and 16KB data cache. 7. It has Quad quad word wide i.e. 256 bits cache data bus, ways set associative cache 8. It provides improved cache hit rate. 9. It supports Multiprocessor system. 10.It Works on 1.0 GHz, 850, 800, 750, 700, 650 MHZ.</p>	<p><i>Any four features 1M each</i></p>
<p>(e) Ans.</p>	<p><b>List and explain advantages of Pentium-2 processor over Pentium – Pro.</b> <b>Advantages of Pentium 2 processor over Pentium pro are as follows:</b> 1. Dynamic Execution Technology: ⇒ Dynamic execution incorporates the concepts of out-of-order and speculative execution. The Pentium II processor’s implementation of these concepts removes the constraint of linear instruction sequencing between the traditional fetch and execute phases of instruction execution. Up to 3 instructions can be decoded per clock cycle. These decoded instructions are put into a buffer, which can hold up to 40 instructions. Instructions are executed from this buffer when their operands are available (versus instruction order). Up to 4 instructions can be executed per clock cycle. 2. Super pipelining: ⇒The pipeline of the P6 processor family consists of approximately 12 stages, versus 5 for the Pentium processor and 6 for the Pentium processor with MMX technology. This enables the Pentium II processor to achieve about a 50% higher frequency than the Pentium processor on the same manufacturing technology. The sophisticated, two-level, adaptive training, branch prediction mechanism of the Pentium II processor is key to maintaining the efficiency of the super pipelined micro architecture.</p>	<p><b>4M</b>  <i>Any four advantages of Pentium -2 processor over Pentium -Pro for 1M each</i></p>

SUMMER – 2019 EXAMINATION  
MODEL ANSWER

Subject: Advanced Microprocessor

Subject Code: 17627

	<p>3. Dual Independent Bus (DIB) Architecture: ⇒ This architecture consists of two distinct buses emanating from the Pentium II processor: the L2 cache bus and the system bus (used for memory and I/O requests). The L2 cache bus speed scales with processor frequency. For the Pentium II processor at 266 MHz, the L2 cache bus operates at 133 MHz, which is twice the speed of Pentium processor systems. The system bus for both processors runs at 66 MHz. The net result is that the Pentium II processor at 266 MHz has about 3 times the peak bus bandwidth of the highest speed Pentium processor system, which has but one bus running at a peak of 66 MHz. Also, since speed of L2 cache accesses is one of the more important system factors in determining overall performance, system performance will scale well with higher processor frequencies. Unlike the Pentium processor's system bus, the Pentium II processor's system bus supports up to 8 outstanding bus requests (4 per processor). This allows more parallelism between processors and I/O, as well as supporting smooth performance scaling to a 2 processor system.</p> <p>4. High Performance Intel MMX Technology: ⇒ Intel's MMX media enhancement technology is a major extension of the Intel Architecture that makes PCs into richer multimedia and communications platforms. This technology introduces 57 instructions oriented to highly parallel operations with multimedia and communications data types. These instructions use a technique known as SIMD (Single Instruction, Multiple Data) to deliver better performance for multimedia and communications computation. Intel processors that provide MMX technology support are fully compatible with previous generations of the Intel Architecture and the installed base of software. ⇒To further improve performance, the Pentium II processor, like the Pentium processor with MMX technology, can execute 2 Intel MMX instructions at a time.</p> <p>5. Write Combining: ⇒ The Write Combining technology of the P6 architecture can be used to achieve very high graphics I/O performance. This feature combines multiple writes to a region of memory (for example, a video controller's frame buffer) declared as WC type into a single-burst write operation. This is well suited for the bus, which is optimized for burst transfers. The combining also leads to burst writes of cache line sizes. These writes are</p>

SUMMER – 2019 EXAMINATION  
MODEL ANSWER

Subject: Advanced Microprocessor

Subject Code: 17627

		<p>further combined by the chipset, leading to high throughput for graphics I/O. The result is enhanced multimedia performance, more realistic full-motion video, and realistic, fast graphics performance.</p> <p>6. Caches: ⇒ The Pentium II processor has 32 KB of non-blocking L1 cache, which is divided into a 16K instruction cache and a 16K data cache. Each of these caches runs at the processor frequency and provides fast access to heavily used data. ⇒ The Pentium II processor has a 512K L2 cache which is unified for code and data, and is non-blocking. There is a dedicated 64-bit bus to facilitate higher data transfer rates between the processor and the L2 cache.</p> <p>7. The floating-point pipeline supports the 32-bit and 64-bit IEEE 754 formats as well as the 80-bit format. The FPU is object code-compatible with the Pentium and 486 processor FPUs.</p> <p>8. The GTL+ (gunning trans-receiver logic) bus provides glue-less support for two processors, giving a cost-effective SMP (symmetric multiprocessing technology) solution. This can be used to significantly enhance OS and application performance in multithreaded or multitasking environments or for functional redundancy checking.</p> <p>9. Testing and Performance Monitoring Features: ⇒ Built InSelf Test (BIST) provides single stuck-at fault coverage of the microcode and large PLAs, as well as testing of the instruction cache, data cache, Translation Look a side Buffers (TLBs), and ROMs. ⇒ IEEE* 1149.1 Standard Test Access Port and Boundary Scan Architecture mechanism allows testing of the Pentium II processor through a standard interface. ⇒ Internal performance counters can be used for performance monitoring and event counting</p> <p>10. Pentium-II works on 233,266,333,350,400 and 450MHZ which is more than Pentium pro.</p>
