#### Important Instructions to examiners:

- 1) The answers should be examined by key words and not as word-to-word as given in themodel answer scheme.
- 2) The model answer and the answer written by candidate may vary but the examiner may tryto assess the understanding level of the candidate.
- 3) The language errors such as grammatical, spelling errors should not be given more Importance (Not applicable for subject English and Communication Skills.
- 4) While assessing figures, examiner may give credit for principal components indicated in the figure. The figures drawn by candidate and model answer may vary. The examiner may give credit for any equivalent figure drawn.
- 5) Credits may be given step wise for numerical problems. In some cases, the assumed constant values may vary and there may be some difference in the candidate's answers and model answer.
- 6) In case of some questions credit may be given by judgement on part of examiner of relevant answer based on candidate's understanding.
- 7) For programming language papers, credit may be given to any other program based on equivalent concept.

	transmission data.	
	Wide dynamic range.	
	<ul> <li>Because of the advances of IC technologies and high speed computers, digital communication systems are simpler and cheaper.</li> </ul>	
	<ul> <li>Digital communication is adaptive to other advance branches of data processing such as digital.</li> </ul>	
	Disadvantages of Digital Communication	
	<ul> <li>The transmission of digitally encoded analog signals requires significantly more bandwidth.</li> </ul>	
	• Digital transmission requires precise time synchronization between the clocks in the transmitter and receiver.	
(b)	State characteristics of communication channel	2M
(6)		2101
Ans:	Characteristics of communication channel.	Any 2
	1. Bit rate	teristic
	2.Baud rate	s 2M
	3.Bandwidth	
	4.Repeater distance	
	5.Channel capacity	
(c)	State sampling theorem.	2M
Ans:	Sampling theorem:         Sampling theorem states that a band-limited signal of finite energy having the highest frequency component <i>fm</i> Hz can be represented and recovered completely from a set of samples taken at a rate of <i>fs</i> samples per second provided that <i>fs</i> ≥ 2 <i>fm</i> .         Where, fs = sampling frequency	2M
	tm = maximum frequency of continuous original signal	

## Subject Name: Digital Communication System <u>Model Answer</u> Subject Code:

7	1	2	
		J	

(d)	List different digital modulation techniques.	2M
Ans:	List of Different Digital Modulation technique:-(i)Amplitude shift keying -ASK(ii)Phase shift keying - PSK(iii)Frequency shift keying - FSK(iv)Quadrature Phase shift keying - QPSK(v)Differential Phase shift keying -DPSK(vi)Quadrature amplitude modulation- QAM	ANY 4 2M
e)	State advantages of TDMA over FDMA	2M
Ans:	<ol> <li>In TDMA since only one station is present at any given time so the crosstalk will avoided this is present in FDMA.</li> <li>The entire channel band which can be allocated to signal channel at given instant of time so the data transmission speed is high.</li> <li>TDMA by default can work well with digital; therefore it can be easily used for digital data transmission.</li> <li>In the TDMA since only one station present at any given time, the generation of inter symbol interference will not take place.</li> <li>Due to the absence of intermodulation products, TWT can be operated with maximum power output or saturation level.</li> <li>It is easier to change the capacity between nodes by simply changing the duration and position of each burst in the TDMA frame. It is very flexible.</li> <li>As the transmission is taking place in bursts, its interception by unauthorized elements is difficult. Hence it is more secure than FDMA.</li> <li>Intermodulation products are absent as there is one carrier only in all time slots.</li> </ol>	Any 2 advanta ges 2M
f)	State the need of multiplexing.	2M
Ans:	<ul> <li>Need of multiplexing</li> <li>In the application like telephony there are large numbers of users involved. It is not possible to lay a separate pair of wires from each subscriber to the other entire subscriber; this is very expensive and practically impossible.</li> <li>In the Process of multiplexing two or more individual signals are transmitted over a single communication channel. Here we used medium as a coaxial cable or an optical fiber cable because of multiplexing bandwidth utilization is possible.</li> </ul>	2M

12

Data unit 1	10101001
Data unit 2	00111001
sum	11100010
one's complement (checksum)	00011101

- pattern sent is ← 10101001 00111001 00011101
- Suppose receiver receives the pattern without any error
- 10101001 00111001 00011101
- the receiver adds the three sections it will get sum as all one's which after complimenting is all zero's and shows that there is no error

Data unit 1	10101001
Data unit 2	00111001
one's complement (checksum)	00011101
sum	11111111
complement of sum	0000000

If the complement of the sum is zero means the pattern is received without error.

### OR

### METHOD 4:-

#### Cyclic redundancy check:

CRC is very effective error detection method. It can detect burst errors that affect odd number of bits. Burst error of length less than or equal to the degree of polynomial. CRC is based on binary division. In CRC a sequence of redundant bits called as CRC remainder is appended to the end of the data unit so that the resulting data unit becomes exactly divisible by a second predetermined binary number. At the destination the incoming data unit is divided by the same number (divisor) if at this step there is no remainder the data unit is assumed to be intact and therefore accepted. If the remainder is non zero then the data unit is discarded.

### For example data is 100100 and divisor is 1101:

At the transmitter ends.

• String of n zero's is appended to the data unit. The number "n" is 1 less than the number of bits in the predetermined divisor, which is n+ 1 bit.

• The newly elongated data unit is divided by the divisor using binary division. The remainder resulting from this division is the CRC.

22428

hence it is bursty communication. It is non-continuous. TDMA cannot send an analog signal directly due to buffering required. It is used for digital data. In this method, all the earth stations share transponder time. Each earth station in the network is allocated a time slot in a periodic sequence. It is a method of time division multiplexing, digitally modulated carrier between participating earth stations within the satellite network through a common satellite transponder. With TDMA, each earth station transmits a short burst of digitally modulated carrier during a precise time slot (called *epoch*) within a TDMA frame. Each earth station's burst is synchronized so that it arrives at the satellite transponder at a different time. Consequently, only one earth station's carrier is present in the transponder at any given time thus avoiding collision with another station's carrier. The transponder is an RF to RF repeater that simply receives the earth stations transmissions, amplifies them and retransmits them in a downlink beam that is received by all participating earth stations. Each earth station receives the bursts from all other earth stations and must select from them the traffic destined only for itself. Compare TDMA and CDMA on the basis of sharing of time and B.W. Synchronization, code d) **4M** word ,guard band and guard time. 1M Ans: each Point Sr. **Parameters TDMA CDMA** No Sharing of time of satellite Sharing of time and Sharing of time & 1 **B.W** Transponder using entire BW bandwidth both. Time synchronization is Code Synchronization is 2 Synchronization essential. required. Code words are required by 3 Code Word No code word is required ground stations. Both guard times and guard Guard band and bands are required if it uses 4 Guard times are required guard time along with TDMA & FDMA. Otherwise not required.

Exp	planation:-
DIS	CRETE INFORMATION SOURCE:
	• The information to be transmitted originates here. These information/messages may be available in digital form or it may be available in an analog form.
	• If it is analog it is sampled and digitized using an A/D converter to make the final source output to be digital in form.
<u>SO</u>	URCE ENCODER :
	• The source encoder therefore reduces the redundancy by performing a one to one mapping of its input bit stream in to another bit stream at its output, but with fewer digits.
	• Thus in a way it performs data compression.
СН	ANNEL ENCODER:
	• The channel encoder is intended to introduce controlled redundancy into the bit stream at its input in order to provide some amount of error- correction capability to the data being transmitted.
DIG	GITAL MODULATOR:
	<ul> <li>The physical channels are basically analog in nature; the digital modulator takes each digital binary digit at its input and maps it, in a one -to - one fashion, into a continuous waveform.</li> </ul>
	<ul> <li>Binary 'zero' at its input is mapped into a continuous signal s<sub>o</sub>(t) and binary 'one' is mapped into another continuous signal s<sub>1</sub>(t).</li> </ul>
	This is called binary modulation.
	<ul> <li>YSICAL CHANNEL:</li> <li>The digitally modulated signal is passed on to the physical channel, which is nothing but the physical medium through which the signals are transmitted.</li> <li>It may take a variety of forms- a pair of twisted wires, coaxial cable, a wave guide, a microwave radio, or an optical fiber.</li> </ul>
тн	E DIGITAL DEMODULATOR:
	• The digital demodulator of the receiver receives the noise corrupted sequence of waveforms from the channel and by inverse mapping tries to give at its output, an estimate of the sequence of the binary digits that were available at the input of the digital modulator at the transmitting end.
TH	E CHANNEL DECODER:
	• The output sequences of digits from the digital demodulator are fed to the channel decoder. Using its knowledge of the type of coding performed by the channel encoder at the transmitting end and using the redundancy introduced by the

(b)	Describe the working of an ADM transmitter with neat block diagram.	4
Ans:	ADM transmitter Block diagram:-	(
	Pulse generator	1
	$p_i(t)$ pulse train with $f_s$ pulses per sec	
	Message signal x(t) Difference $e(t)$ $p_o(t)$ Delat-modulated output $p_o(t)$ $p_o$	
	Staircase	
	signal x(t) Intergrator Amplifier	
	Gain control R signal Square-law device	
	$\hat{m}(t)$ Comparator and $o S_0(t) = e(k)$

irrespective of whether it is positively charged or negatively. Due to the squaring device (square law device), the amplifier gain will be increased no matter what the polarity of the capacitor voltage is. The net result is an increase in step size and a reduction in slope-overload distortion as shown in figure (c) Explain TDM technique with relevant diagram. **4M** Ans: (Block diagra TIME DIVISION MULTIPLEXING (TDM): m TDM is a digital multiplexing technique in which many signals are transmitted for very 2M, short time (time slot) over common transmission channel. Here each signal can utilize Worki ng the entire bandwidth of the channel. Figure 5.6 illustrates the concept of TDM. =2M) Here each signal will be transmitted for a short duration of time. One cycle or frame is said to be complete when each time slot is dedicated to each signal. With n input signals (transmitting devices), each frame has n time slots, with each slot allocated for carrying data from a specified device. The TDM signal in the form of frames is transmitted on the common communication medium. TDM can be used to multiplex analog or digital signals but it is suitable for digital signal multiplexing. DATA FLOW Frame 1 Frame 2 м D 3 2 4 3 2 1 U Е Μ х U Time slot х in each frame = Time 1 slot ..... 2 ..... Ν Frame Frame Conceptual Diagram of TDM OR **BLOCK DIAGRAM OF TDM SYSTEM:** TDM is a digital multiplexing process that can be applied when the data capacity of the transmission medium is greater than the data rate required by the transmitting and receiving devices. In such cases, multiple transmissions can occupy a single link

	<ul> <li>3. PN sequence generation at the transmitter &amp; receiver generates identical PN binary valued sequence</li> <li>4. PN sequence is impressed on the information signal at the modulator (Tx)</li> </ul>	
	<ul> <li>and remove from the received signal at the Demodulator.</li> <li>5. Synchronization of the PN sequence generator at the receiver with the PN sequence contained in the incoming received signal is required in order to demodulate the received signal.</li> </ul>	
	Prior to the transmission of information Synchronization may be achieved by transmitting a fixed PN sequence pattern which the receiver will recognize in the presence of interference with high probability.	
(e)	Encode binary sequence 10110110 using unipolar-RZ ,polar-NRZ,AMI and differential Manchester line coding techniques	4M
Ans:	Data IDPUT TE Unipolar RZ TE TE TE TE TE TE TE TE TE TE	1M each
